Abstract

The paper presents a new type of modified glassy carbon paste electrode with different Co- ferrites. First part of this work was the preparation of ferrites by five different methods such as hydrothermal, ultrasound and microwave-assisted hydrothermal, mechanochemical and sol-gel synthesis. Ferrite nanoparticles were characterized using scanning electron microscopy (SEM) and X-ray diffraction (XRD). They were used for preparation new modified glassy carbon paste electrode (CoFeMGCPE). The electrode was used for determination of nanomolar level of copper ions in waste waters using electrochemical methods such as differential pulse anodic stripping voltammetry, DPASV. A significant increase in current was achieved at the modified electrode in comparison with the bare glassy carbon paste electrode. Detection limit for the proposed electrode was 30nM Cu when percentage of modifier was 3%, pH 4.5, deposition potential -0.3 V and deposition time 4min. This electrode was successfully applied for determination of copper ions in waste water without any pre-treatment.

Key words: cobalt ferrite, copper, modified electrode, glassy carbon paste, electrochemistry

1. INTRODUCTION

The development of new functional nano-sized ferrites is relentlessly growing, not only due to their special magnetic properties, but due to their unique properties and various ideas about their potential uses in the modern scientific fields. Polycrystalline spinel ferrites show many interesting physical and chemical phenomena, such as high electrical resistivity, high Curie temperature, large magnetocrystalline anisotropy, high coercitivity, mechanical hardness, chemical stability, and temperature specific saturation magnetization, and so forth (Lu et al. 2007). Therefore, nano-sized ferrites can be used as magnetic devices and catalysts. They also play an important role in ferrofluid technology and biomedical fields. In the last years, their usability in electrochemical purposes has been widely investigated (McCurrie et al. 1994, Konishi et al. 2004). Cobalt ferrites present a promising candidates for electrode material due to their similar electronic properties, mechanical strength and electrochemical performances, providing significant improvements of electrodes for determination of metal ions in waste water, and some organic and biological active substances (Janegitz et al. 2009 and Kalcher et al. 2006). Nowadays, great effort has been devoted to the electrochemical determination of toxic metals at new different electrodes (Kalcher et al. 1985). Carbon paste electrodes (CPE) have been widely used in electrochemistry since they are chemically inert, suitable for different types of analysis and can be simply modified (Kalcher et al. 1990).

It is well-known fact that characteristics of ferrites strongly depends on the synthesis methods. There are many well-known and easily modified methods for their preparation, such as co-precipitation, ball-milling, sol-gel, pyrolysis etc. Among them, co-precipitation is used widely because of its low cost and moderate operation conditions. Some new improved co-precipitation methods have been developed, such as sonochemical and microwave-assisted co-precipitation.
In order to find the most efficient modifier of the CPE, synthesis of mixed Co/Ferrites was performed by five different methods: hydrothermal (Byrappa et al. 2001), ultrasound (Suslick et al. 1989), microwave-assisted hydrothermal (Bilecka et al. 2010), mechanochemical (Manova et al. 2009) and sol-gel (Song et al. 2010). Moreover, obtained materials were characterized by XRD and SEM analysis. The usability of Co-Ferrites as modifiers of CPE for the determination of Cu in waste water was studied and the electrochemical properties were investigated by fabricating a simple and sensitive electrochemical sensor based on Co-Ferrites/CPE.

2. MATERIALS AND METHODS

2.1. Apparatus

The voltammetric changes of the CME were measured with the Metrohm 797 VA Computance instrument (Herisau, Switzerland). The triple-electrode system consisted of a working electrode, our modified GC paste electrode, a reference Ag/AgCl, KCl (3 M) (Model 6.0728.010) and an auxiliary separate platinum rod electrode (Model 6.0340.000). All measurements were taken at ambient temperature. During the measurements the sample was stirred.

The morphology of the ferrite powders was examined by SEM Joel JSM-6610LV. The X-ray powder diffraction (XRPD) analysis was conducted using Philips PW-1710 automatized diffractometer with graphite monochromator and a Xe-filled proportional counter, using a Cu-tube operated at 40 kV and 30 mA. Data were collected in the 2θ range 15-60° with a counting time of 2.5 s/step and a step size of 0.05°. A fixed 2θ divergences and 0.2 mm receiving slits were used.

2.2. Reagents

All reagents used, were p.a. quality, obtained from Sigma-Aldrich and Alfa Aesar suppliers.

Cu(II) stock solution (1*10⁻³ mol/L) were prepared from CuSO₄•5H₂O, and standardized complexometrically. Working solution for ASV investigations were prepared by diluting the appropriate amount of the stock solutions in electrolytes. Acetate buffer solutions 0.1 mol/L (different pH) were used to control the pH. All other reagents were of analytical grade. Ultrapure water (Milli-Q plus 185 system, Millipore) was used in all experiments.

3. EXPERIMENTAL

3.1 Synthesis of electrode materials

3.1.1 Hydrothermal synthesis of Co-ferrites

Synthesis was slightly modified procedure described by Almeida et al. (2012). FeCl₃x6H₂O and CoCl₂x6H₂O were mixed in stoichiometric (2:1 molar) ratio in distilled water. With the vigorous stirring, aqueous solution of salt were heated, and the pH was adjusted to 9.5 with NaOH 10% solution. The synthesis temperature being maintained at 90-95°C for 1 hour under vigorous magnetic agitation. Ferrite solution was cooled to room temperature and filtered on a Buchner funnel, washed with distilled water (3x10 ml, until chloride was out) and with 0.1M solution of HNO₃ (3x10ml). Precipitate was dried at 105°C.

3.1.2 Microwave-assisted hydrothermal synthesis of Co-ferrites

Co ferrites were prepared under microwave-hydrothermal condition (D’Arrigo et al. 1998) Co(II) and Fe(III) nitrates were dissolved in ethylene glycol in stoichiometric ratio, neutralized with ammonia, and microwave treated at 2.45 GHz in Teflon reaction flask (Ethos Milestone). Powder was filtered on a Buchner funnel, washed with ethanol (3x10ml), and dried at 105°C.

3.1.3 Ultrasound synthesis of Co-ferrites

Synthesis was slightly modified procedure described by Goswami et al. (2013). Co(II) and Fe(III) chlorides were dissolved in pure water in stoichiometric ratio, and mixed, stirred and heated to 80°C
for one hour in ultrasonic bath Sonorex RK255H, operated at 35 kHz. Dark precipitate formed. It was filtered on a Buchner funnel and washed with pure water several times (until chloride was out) and with 0,1M solution of HNO₃ (3x10ml). Powder was dried at 105°C.

### 3.1.4. Mechanochemical synthesis of Co-ferrites

The synthesis (Manova et al. 2005) was performed by two steps: co-precipitation and mechanical milling of the co-precipitated precursors. The starting materials used were Fe(NO₃)₃·9H₂O, Co(NO₃)₂·6H₂O and Na₂CO₃. In the co-precipitation phase, a 0.5M solution of metal salts containing Co and Fe were taken in a stoichiometric molar ratio (1:2). Mixtures of cobalt and iron hydroxide carbonates precursors were formed when a 1M sodium carbonate solution was added at pH 9. The precipitates were washed and dried at 105°C for 3 h. The as-obtained precursors were milled using a PM 100, RETSCH planetary mill in a hardened steel vial of 200 cm³ volume, filled with 10 hardened steel balls with a diameter of 8mm. The mass of powder mixtures was 5 g and the balls to powder mass ratio was 20:1. The milling was carried out in air atmosphere without any additives. Milling time was 10h, at 500 rpm (Manova et al. 2009).

### 3.1.5. Solid state synthesis of Co-ferrites

To obtain Co-ferrite by sol-gel method (Shinde et al. 2016) the following chemicals were used: Co(NO₃)₂·6H₂O, Fe(NO₃)₃·9H₂O, KCl and PEG 1500. Mixtures of salts, made in stoichiometric ratio were made in a minimum amount of distilled water and heated and mixed in an ultrasonic bath (Eurosonic 4D, 35 kHz), at 80°C. The solution thus obtained was stirred for 10 minutes and then citric acid followed by ethylene glycol was added. The solution was again stirred till gel formation. The mixture was heated on the hot plate till it ignites and continues heating 4 h on 300 °C. Obtained ferrite nanopowders were washed with pure water several times (until chloride was out) and with 0.1M solution of HNO₃ (3x10ml). Powder was dried at 105°C.

### 3.2. The fabrication of the modified carbon paste electrodes (CoFeGCPE)

Bare carbon paste electrode was prepared by carefully hand mixing 380 μL of paraffin oil with 1 g of graphite powder in anagate mortar. After standing overnight a portion of the resulting paste was packed into the end of a Teflon tube (an inner diameter 5 mm, outer diameter 10mm) and the surface was polished using a PTFE plate. The carbon paste was modified by adding 3 % (m/m) of Co-ferrite. The amount of modifier was selected according to our experience and previously described articles (Schachl et al., 1997). Whenever regeneration was required, a layer of the surface was removed and replaced by fresh paste. Electrical contact was made with a copper wire the center of the tube (Mou et al., 2013)

### 3.3. Analytical procedure

Co-ferrites, synthesized by described ways were used as a modifiers of carbon paste electrodes in order to improve the sensitivity of the electrodes, and the current signal. The electrode was used for the determination of nanomolar amounts of copper 2+ ions in waste water by differential stripping voltammetry (Carnival, DPASV). Ferrite nanoparticles were characterized using scanning electron microscopy (SEM) and X-ray powder diffraction (XRPD) and were determined by electrochemical parameters. Thus prepared electrodes show the detection of copper 2+ ions and successfully applied for the determination of copper ions in water samples.

All measurements were carried out in acetate buffers different pH value. The potential range was set from -0.4 V to 0.2 vs. Ag/AgCl electrode with scan in anodic direction. The electrochemical parameters were optimized by differential pulse anodic striping voltammetry. A series of standard solutions of Cu(II) for calibration curves and the recovery studies was measured by DPASV under the optimized working parameters describe above. The influence of some interference was included. The same procedure, with best modifier and best parameters, was applied to natural water sample and the results were compared with other reference method.
3.4. Optimization of analytical conditions

In order to obtain the optimum experimental conditions, some variables affecting the peak current i.e. pH, the amount of modifier, accumulation time, accumulation potential for a $1.0 \times 10^{-6}$ mol/L Cu(II) solution were studied.

Table 1

The best conditions for determination of copper at the bare glassy carbon electrode using DPASV were determined [Table 1 and Fig. 1]. The highest value for peak current for cobalt at bare glassy carbon electrode was at pH 4.5 (acetic buffer), deposition potential -0.4 V and deposition time 3min for $10^{-5}$M concentration of copper. After that the best percentage of the CoFe$_2$O$_4$ modifier were investigated. At the same condition as the bare glassy carbon electrode the percentage of 3% CoFe$_2$O$_4$ has the highest current for determination of copper. According to this, all electrodes were prepared with 77% of glassy carbon powder, 3% of modifier, and 20% of paraffin oil.

3.5. Preparation of water samples

The water samples were obtained from three rivers (Table 2, Kolubara W1, Gradac W2 and Djetinja W3 from Western Serbia) without any pre-treatment. Each sample was filtered to obtain a clear filtrate, transferred to volumetric flask, and stored in a fridge (4°C). The determination of copper was performed by mixing 2 mL of river water with addition of calculated amount of Cu standard, with 8 mL of supporting electrolyte solution.

4. RESULTS AND DISCUSSION

4.1. Characterization of Co-ferrites

Result of XRD analysis [Fig. 2] shows that all ferrite materials shows high ferritization ratio, and the line widths confirms ultra-fine structure of them.

![XRD analysis](image)

**Figure 2**

From the pictures obtained by SEM [Fig. 3], it is clear that a sample of Co ferrite [d], obtained by microwave-assisted hydrothermal method have better defined ultra-grained surface than others, obtained by other ways (hydrothermal [a], ultrasound assisted [c], mechanochemical [b] and sol-gel[e]). That may by a reason for its highest reactivity.
5. CONCLUSION

The preparation of Co-ferrite modifiers of glassy carbon paste electrode and its analytical application for determination of copper in natural waters samples was investigated. The cobalt ferrites were synthesized by five different ways and characterized. The modified electrode with low detection limit were successfully applied for determination of copper ions in natural waters.
